

Inchcolm Island & Forth Bridge - Grown-ups

UK Family Tour

The Forth Bridge: Engineering as Public Reassurance

The cantilever railway bridge your boat passes under is a UNESCO World Heritage Site and arguably the most influential structure of the Victorian age. Context explains its extraordinary appearance: in December 1879, the Tay Bridge — then the longest in the world — collapsed in a storm, taking a train and everyone aboard, about fifty-nine people, into the river. Its designer, Thomas Bouch, had a Forth crossing already underway; his contract was cancelled and his reputation destroyed. Benjamin Baker and John Fowler’s replacement design was engineered to be not merely safe but demonstratively safe — a structure whose strength is legible to a layman at a glance. The numbers remain absurd: fifty-three thousand tonnes of open-hearth steel, the first major British structure to use it; roughly six point five million rivets; towers a hundred ten meters high; and a workforce of around four thousand five hundred “briggers,” of whom at least seventy-three died — a rescue-boat system saved several who fell. Baker explained the cantilever principle with a famous living model: two men on chairs with outstretched arms supporting a third seated between them. Opened in March 1890 with the Prince of Wales driving home a gold-plated final rivet, it still carries around two hundred trains a day. “Painting the Forth Bridge” entered the language as the endless task, though modern glass-flake epoxy ended the truth of it — the 2011 coat is rated for decades. Note the neighbors: the 1964 Forth Road Bridge and 2017 Queensferry Crossing alongside make this firth a three-century museum of long-span engineering in a single view.

The Human Cantilever

In 1887, three years before the bridge opened, Benjamin Baker faced a very Victorian problem. How do you convince a nervous public, and a skeptical press, that a shape nobody had seen before can be trusted with their lives? His answer became one of the most famous images in all of engineering. He sat two men on ordinary chairs, a little apart, and had each stretch out his arms gripping a wooden pole, with a heavy stack of bricks piled on the outer side as an anchor. Then, in the empty space between them, held up by nothing but their outstretched arms and a short beam across the gap, a third man sat down in mid air. That living, breathing model was the Forth Bridge. The men’s arms, pulling, were in tension, doing the work of the bridge’s upper steel bars. Their bodies and the poles, pushing down and out, were in compression, doing the work of the great lower tubes. The piles of bricks were the weighted end spans reaching back over the approach viaducts. Put a load on the man in the middle and you could watch, in real time, exactly which parts strained and which parts squeezed. There is a lovely piece of theatre in the casting, too. The man in the centre was Kaichi Watanabe, a young Japanese engineer who had trained in Glasgow and worked on the bridge itself. Baker and Fowler chose him deliberately, a graceful nod to the idea that the cantilever, an arm reaching out and balanced by a counterweight, had ancient roots in the timber brackets of the East. So the photograph you may have seen, of two whiskered gentlemen holding a slim young man aloft on their arms, is not a music-hall joke. It is a physics lecture, a diplomatic courtesy, and a masterpiece of public relations, all at once. And it worked. After the Tay Bridge disaster had shattered the country’s faith in engineers, Baker understood that his bridge had to be not merely safe but legibly, visibly, arguably safe, a structure whose logic a Member of Parliament or a Fife farmer could

grasp at a single glance. When you look up now at those three double cantilevers marching across the firth, picture the men on the chairs. Every diamond of steel above you is simply one arm reaching out, and another arm holding it back.

The Numbers That Still Astonish

Even now, with a century of larger structures behind us, the Forth Bridge has a way of stopping you. Its two main spans each leap five hundred and twenty one metres from tower to tower. When the bridge opened in 1890, those were the longest spans of any bridge on Earth, and they held that record until 1917, when the Quebec Bridge in Canada finally reached a fraction further. More than a hundred years on, the Forth's spans are still the second longest cantilever spans in the world. Look at where the central tower stands. Not on some purpose-built pier in open water, but on Inchgarvie, a real island in the middle of the firth, a rocky little outcrop that once carried a castle and a quarantine hospital and now bears thousands of tonnes of Scottish steel. The railway runs forty six metres above the high tide, roughly the height of a fifteen storey building, and that was no accident either. The Admiralty demanded it, so that the tallest warships of the age could pass beneath with their masts intact. The three great towers rise to a hundred and ten metres. And then there is the paint. For more than a century, painting the Forth Bridge was the English language's favourite image for a task without end, the crews forever creeping from one end to the other only to turn round and start again. It was roughly true, once. It is not true now. Between about 2002 and 2011, at a cost of some one hundred and thirty million pounds, the entire structure received a triple coat of glass flake epoxy, the same sort of coating used on North Sea oil platforms, which bonds to the steel and is expected to last at least twenty five years. So the idiom is now, strictly speaking, a lie, though a beloved one the guides will happily keep repeating. What has not changed is the traffic. Around two hundred trains still cross every single day, rumbling over the same lattice of steel, well over a century after the briggers hammered home the last rivet. It remains a working railway bridge, carrying real people to real places, not a monument behind a rope. And that, in the end, is precisely what makes it a monument.

Three Bridges, Three Centuries

Turn your head slowly as the boat clears the shadow of the railway bridge, and you are looking at one of the finest short courses in the history of civil engineering to be found anywhere in the world. Three great crossings side by side, each the answer to its own century's question. Nearest and oldest is the cantilever of 1890, built for steam trains and built, above all, to be trusted. Beside it stands the Forth Road Bridge of 1964, a graceful steel suspension bridge whose main span of just over a thousand metres made it, when it opened, the longest suspension span in the world outside the United States, and the fourth longest anywhere. For half a century it carried the cars and lorries the railway never could. But a suspension bridge lives and dies by its main cables, and in the two thousands inspectors found corrosion and broken wires hidden deep inside them, with traffic far heavier than the nineteen sixties had ever dreamed of. Rather than gamble on the repair, Scotland built a third crossing. The Queensferry Crossing opened in 2017, its slim towers trailing cables like the strings of three enormous harps. At just over two point seven kilometres it is the longest three-tower cable-stayed bridge in the world, the elegant modern sibling to the muscular Victorian giant upstream. There is a lovely human thread running under all this steel. The contractor who built the 1890 railway bridge, William Arrol, a self-taught Paisley blacksmith's boy, also built the replacement Tay Bridge and, down in London, Tower Bridge. One man's firm raised the bridge in front of you and one of the bridges your family will cross in London. So this single view holds a hundred and twenty seven years of ambition, from coal smoke to the motorcar to a future of lighter, longer, more slender spans, all crossing the same stubborn stretch of grey water for the same simple, human reason. People on one side have always wanted, very badly, to reach the other.

Inchcolm Abbey: Scotland's Best-Preserved Monastery

Inchcolm's foundation legend has Alexander the First storm-driven ashore in 1123 and sheltered for three days by a hermit living in the island's tiny stone cell — which still stands — leading the king to vow a monastery to St Columba; his brother David the First, Scotland's great monastic patron, delivered on it with a priory of Augustinian canons, raised to abbey status in 1235. The island's dedication to Columba is why it's called the Iona of the East, and burial here carried Iona-like prestige — the abbey church held the tombs of nobles including a Bishop of Dunkeld, and Shakespeare knew the association: in *Macbeth*, defeated Norwegians pay ten thousand dollars “to their general use” for leave to bury their dead on “Saint Colme's ynch.” Isolation was the abbey's protection and its curse: English raiders plundered it repeatedly in the Wars of Independence era — one chronicle tells of raiders returning loot after their ship foundered, taken as the saint's displeasure — but the Reformation's demolition crews largely never bothered crossing the water, leaving the most complete medieval monastic complex in Scotland. The thirteenth-century chapter house with its stone vault and the intact cloister walk are the highlights, along with a rare survival upstairs: a fragment of medieval wall painting showing a funeral procession of hooded mourners. Climb the tower if the group's knees permit — the view assembles the whole day: bridges west, Edinburgh and Arthur's Seat south, the firth opening east toward the sea.

The Literary Island

For all its stones, Inchcolm's strangest legacy may be made of words. In the fourteen forties, in the very buildings you are walking through, the abbot of Inchcolm, Walter Bower, sat down to write the *Scotichronicon*, a vast history of the Scots from mythical origins to his own day. It became the great chronicle of medieval Scotland, the source, and sometimes the inventor, of much that later ages would believe about their own past. And here the island performs a quiet trick. The Scottish chronicle tradition that Bower helped shape flowed downstream. It was gathered and embroidered by the historian Hector Boece, then translated and folded into Raphael Holinshed's *Chronicles* in England, the very book William Shakespeare kept at his elbow when he wrote *Macbeth*. So when Shakespeare needed a name for the place where the beaten Norwegians must pay for their defeat, he reached for a real island in the Firth of Forth. In the second scene of the play, the messenger Ross reports that the Norwegian king Sweno is suing for peace, and that the Scots would not even grant his men burial until, in Shakespeare's words, he disbursed at Saint Colme's Inch ten thousand dollars to our general use. Saint Colme's Inch is this island, Inchcolm, the inch, or island, of Saint Columba. There is a charming anachronism buried in the line, since dollars, really German thalers, did not exist in eleventh-century Scotland. But the deeper detail rings true, because Inchcolm genuinely was a prestige burial ground, the Iona of the East, where nobles paid handsomely to be laid to rest near the bones of a saint. So a poet's invented tribute sits on top of a real medieval trade in holy ground. The point, though, is the loop. A monk on this island wrote the history that fed the chronicles that fed the playwright who put the island back into one of the most famous plays ever written. Stand here in the cloister and you are standing where a small, damp, salt-scoured Scottish monastery reached out across three centuries and four hundred miles and touched the London stage. Not bad for a place a hermit once shared with a single cow.

Why the Ruin Is So Complete

Most Scottish monasteries come down to us as romantic fragments, a lone gable here, a row of broken arches there, because after the Reformation of 1560 they were quarried for building stone, stripped of their lead and timber, and left to the weather. Inchcolm is the great exception, and the reason is the water all around you. Demolition crews, and thrifty neighbours hunting for free masonry, rarely thought

it worth loading a boat and crossing a tidal firth for it. Isolation, which had always been the island's discipline, became its salvation. So this is the most complete medieval monastic complex in Scotland, and it rewards slow, deliberate looking. Start with the chapter house, the octagonal room where the canons gathered each morning to hear a chapter of their rule, confess their faults, and take their orders for the day. It still keeps its stone vault and its roof, the finest chapter house of its date in the country, and the acoustics inside are worth testing with a single word. Walk the cloister next. Three of its four covered walks survive, making it the most complete cloister in Scotland, and you can still read the daily geography of the place, the path to the church, the way to the refectory where they ate in silence, the stair up to the dormitory where they slept. The refectory and dormitory ranges stand too, a rare chance to sense a whole monastery rather than a picturesque fragment. Then, upstairs in a tomb recess, look for the real treasure, a fragment of thirteenth-century wall painting showing a funeral procession, a line of hooded mourners, a rare survival of the bright colour that once covered nearly every surface in a medieval church. And at the north-western corner, find the small stone cell, quite possibly the very hermitage that sheltered King Alexander in 1123 and gave the island its abbey in the first place. Today Historic Environment Scotland keeps the roofs sound and the grass trimmed, but the essential caretaker was always the sea. Everything you can lay a hand on here survived for one gloriously unromantic reason. It was simply too much trouble to steal.

The Hog-Backed Stone and the Island's Norse Dead

Before you leave, step into the small visitor centre and find the one object here that is older than every stone of the abbey around it. It is a long, heavy slab of pale sandstone with a curved back, like the ridge of a roof, and it carries a name as memorable as its shape. It is a hogback stone, and it was carved in the middle of the nine hundreds, close to two hundred years before King Alexander was ever storm-driven ashore. It was found on a raised patch of ground on the island, marking a grave.

A hogback is one of the strangest and most touching forms in all of early medieval sculpture. It is a tomb carved to look like a house. The curved upper edge is the ridge of a Norse long-hall, and along the sloping sides you can still make out rows of overlapping tiles or shingles, like the scales of a fish, exactly as they would have covered a real timber roof. At one end there is a very eroded animal, a beast, seeming to grip or guard the whole thing, cousin to the carved dragons the Norse set on their ships and gable ends. The idea is quietly beautiful. The dead were given a stone home shaped like the halls they had lived in.

Hogbacks are the signature of the Norse settlers who came to northern England and southern Scotland in the Viking age, put down roots, farmed, and in time took up the Christian faith. And this one wears its faith openly. On one face is the figure of a man with his arms flung wide and a spear at his side, and on the other, the traces of a cross, each framed by carved pillars. So this is not the marker of a heathen raider. It is the grave of a Christian of Norse blood or Norse taste, laid to rest on this island when it was already holy, generations before the Augustinians arrived.

Keep the stone in mind, because later on your journey, when you walk the reconstructed streets of Viking York, you will meet these same people again, the settlers rather than the plunderers. You have simply met them here first, on a small island in the Forth, in the shape of a stone house built for the dead.

The Armed Island: Two World Wars on Inchcolm

The military concrete threaded through Inchcolm isn't an intrusion on the island's story — it's the same story, resumed. The logic that made this a holy refuge, its commanding position in the Forth, made it a keystone of the firth's defenses when the Royal Navy's great anchorage at Rosyth and the fleet base upstream needed protecting. In both World Wars the island was garrisoned — gun batteries, searchlight posts, engine rooms, barracks for around a hundred men, anti-submarine and anti-boat defenses, all integrated into a layered system of fortified islands (Inchgarvie, Inchmickery, Cramond) and booms stretched across the estuary; Inchmickery, visible nearby, was built up so heavily it's said to have been mistaken for a warship in silhouette, allegedly by design. The tunnel through the island's eastern hill, cut in the First World War to move men and ammunition under cover, is walkable and atmospheric. The Forth saw the war's first act and last scene: in October 1939, the first German air raid on Britain targeted warships here — bombs fell within sight of this island, and the first enemy aircraft shot down over Britain came down nearby — and in November 1918 the German High Seas Fleet steamed into this very firth to surrender, seventy warships passing the island into captivity. Today the garrison is gulls — genuinely assertive in chick season, so keep to paths — plus grey seals hauled out on the skerries and, with luck, puffins commuting past the boat.

The Guns of Inchcolm, Up Close

The military ruins you are climbing over have precise dates and a precise job. On the sixteenth of March 1915, some seventy men of the Royal Garrison Artillery crossed from Leith and took possession of the island. Inchcolm's task was to help slam a door across the Firth of Forth. Stretched between the islands ran an anti-submarine boom, a chain of nets and obstacles meant to keep German U-boats and torpedo craft out of the great naval anchorage upstream, and the guns on Inchcolm existed to cover the gap where friendly ships were let through. At its wartime peak the island mounted eight twelve-pounder quick-firing guns, the light, fast, rapidly aimed weapons you use against small, nimble targets rather than battleships. Two sat in the western part of the island and six were grouped around the summit of the eastern hill, trained north, north-east and south-east so that between them they swept every approach. Alongside them stood the searchlights, formally called Defence Electric Lights, mostly out at the eastern tip, ready to pin a night intruder in a beam of glare for the gunners. To arm all this quickly and under cover, in 1916 and 1917 the 576 Cornwall Works Company of the Royal Engineers drove a brick-lined tunnel clean through the eastern hill, linking the ammunition stores on the sheltered side to the batteries on the exposed side, with a ventilation shaft rising at its midpoint. That is the atmospheric passage you can walk today. As you go east, past the gun rings and the searchlight housings and into the dark of the tunnel, remember that around a hundred men lived out here in the wind and the wet, watching the same water the monks once watched, for a threat the monks could never have imagined. The island was mothballed after 1918 and then reoccupied in 1939, when the boom went back across the firth and the whole grim routine began again. Two world wars, one small island, and the same unbroken logic. Whoever holds Inchcolm helps hold the road to Edinburgh.

Rosyth and the Grand Fleet

To understand why anyone would bother to fortify a small abbey island, look upstream, past the bridges, toward Rosyth. Britain began carving a great naval dockyard out of that shore in 1909 and opened it in 1916, precisely because the Firth of Forth offered a deep, defensible anchorage on the North Sea coast, staring straight across the water at the German fleet. Through much of the First World War the battlecruisers based here steamed out to spar with the enemy, and several of the ships that fought at

Jutland in 1916 called this firth home. Then, in April 1918, came the climax. Admiral Beatty brought the entire Grand Fleet, the most powerful concentration of warships in the world, down from Scapa Flow to the Forth, mooring the battleships above and below the railway bridge. Picture that from Inchcolm, a grey steel forest of dreadnoughts filling the firth beneath the red span. It was to shelter exactly this that the little island bristled with guns and searchlights. The story did not end in 1918. Rosyth went on building and repairing warships right through the twentieth century and into our own, and here is the detail worth carrying away. Both of the Royal Navy's newest aircraft carriers, HMS Queen Elizabeth and HMS Prince of Wales, the largest warships Britain has ever built, were assembled at Rosyth in the twenties, floated together from giant blocks made in shipyards all around the country. When the finished Queen Elizabeth first sailed out to sea, she had to pass beneath the Forth Bridge your boat is crossing under, and she cleared it with only a few metres to spare, her mast specially designed to fit under the Victorian steel. So the same stretch of water that gathered the Grand Fleet in 1918 launched the modern fleet's flagship a century later, both of them threading past this one small island of praying monks and rusting guns. Inchcolm has now spent eight hundred years watching the most important warships of every single age go by, and it has never once had to fire a shot in anger to do it.

The Forth's First Air Raid

The guns you have been climbing over were built to stop a threat coming across the water. But the most dramatic day this firth ever saw came, instead, out of the sky, and Inchcolm had a front-row seat. It was the sixteenth of October 1939, barely six weeks into the Second World War, and it has gone into the histories as the Battle of the River Forth.

Twelve German bombers, Junkers eighty-eights, came in from the North Sea in flights of three, led by a Luftwaffe captain named Helmuth Pohle. Their target was the Royal Navy, the warships gathered around Rosyth and the great bridge, among them the cruisers Southampton, Edinburgh and the destroyer Mohawk. There was a curious restraint on that first attack. Hitler had given strict orders not to bomb the dockyard itself or the ships tied up in it, for fear of killing civilians and hardening British resolve too soon, so the bombers were allowed to go only for ships out in the open water. This was the first time German aircraft had attacked Britain itself in the war. It was happening directly over the estuary you are sitting in.

And Scotland's own airmen were waiting. Spitfires of two auxiliary squadrons scrambled to meet them, six-oh-two, the City of Glasgow squadron, and six-oh-three, the City of Edinburgh, weekend fliers turned loose on the real thing. In the running fight that followed they brought two of the Junkers down into the cold Forth, and in doing so claimed the first German aircraft shot down over Britain by the Royal Air Force since the First World War. A day of firsts, bought at a price, for sixteen sailors were killed aboard the ships below.

Here is the detail that gives it a chill. Ordinary people watched the whole thing happen. From tenement windows in Edinburgh, from the streets, from the shore at Fife, crowds stood in the open and stared up at the twisting specks, the puffs of anti-aircraft fire, the planes falling, as if a newsreel had come to life above their heads. Nobody yet had the habit of running for shelter. Stand on Inchcolm and look up, and you are under the same patch of sky. The island's whole reason for being, all those guns and searchlights and the tunnel through the hill, was to guard against enemies on the sea. The future arrived overhead instead, and it arrived first, of all the places in Britain, right here.

The Queen's Ferry: Nine Centuries of Crossing

Notice where you set out from. The whole reason there is a pier here, a town here, and three of the world's great bridges gathered in a single view, is that this is the pinch of the Forth, the narrowest place a wide and dangerous firth ever lets you cross. For a thousand years, whoever wanted to get from Edinburgh to the old capital at Dunfermline, or on to the shrine at Saint Andrews, came to this exact squeeze of water to do it.

And the crossing has a name, and the name has a queen. In the late eleventh century, Queen Margaret, the devout wife of King Malcolm the Third, established a ferry across the firth here for pilgrims, and paid for it herself so that the poor could cross without a fare. That was the Queen's Ferry. It is why the little town under the rail bridge is called South Queensferry, why the village on the Fife shore opposite is North Queensferry, and why the newest bridge is the Queensferry Crossing. A single act of medieval charity named the whole place, and everything you can see from this deck.

Boats worked that crossing, in an unbroken line, for roughly nine hundred years, right up until the Forth Road Bridge opened in 1964 and finally made the ferry unnecessary. Your Maid of the Forth is the last echo of it, still carrying passengers across the Queen's own water, though today you are crossing for the pleasure of it rather than to save your soul.

Saint Margaret's Passage

The queen who gave this crossing its name is one of the more remarkable figures of the eleventh century, and her story is worth the telling. Margaret was born into the old royal house of England, a granddaughter of a Saxon king, and spent part of her childhood in exile in Hungary. When the Normans conquered England in 1066, her family fled north by sea, and tradition says a storm drove their ship into the Forth, to a sheltered inlet on the Fife shore that is still called Saint Margaret's Hope to this day. There she met, and before long married, the King of Scots, Malcolm the Third, the very Malcolm who ends Shakespeare's Macbeth on the throne.

She turned out to be a formidable queen. She reformed the Scottish church, fed and washed the poor with her own hands, read scripture to her rougher husband, and by all accounts civilised a hard court considerably. And she was intensely devoted to pilgrimage. She wanted the faithful to be able to reach the shrine of Dunfermline, which she and Malcolm made their favourite seat, and beyond it the great pilgrim road to Saint Andrews. So she founded a ferry across the Forth for them, and here is the part that made it beloved. It was free. She built hospices, rest houses, on both shores, kept them stocked with food and attendants for travellers and the poor, and provided the boats to carry pilgrims over and back without ever charging a passage. The monks of Dunfermline ran the service. She herself crossed so often that the ferry, the inlet, and eventually two whole towns took her royal title.

Margaret died in 1093, within days of hearing that Malcolm had been killed in battle, and the story goes that she died as much of grief as of illness. The church made her a saint in 1250, and Scotland has never quite let go of her. Dunfermline Abbey, which grew from her foundation, became the burial place of Scottish kings, Robert the Bruce among them. And her ferry outlived her by nearly nine centuries, plying this water until 1964. When you step ashore today, remember that you are completing a journey a queen arranged, out of kindness, for strangers she would never meet, a thousand years ago.

The Islands of the Forth

As the boat works its way out to Inchcolm, the firth scatters a whole archipelago of little islands and rocks around you, and each one has a job, a name, and usually a story. The word to know is inch, from the Gaelic innis, meaning simply an island. So Inchcolm is Columba's island, Inchgarvie the rough island, Inchmickery something like the island of the priest.

Look first at Inchgarvie, the rocky outcrop directly beneath the middle of the great rail bridge, carrying one of its towers. Long before the engineers arrived it held a castle, and at various times a prison and a quarantine station for plague-stricken ships, a lonely rock for keeping unwanted things at arm's length. Then there is Inchmickery, low and grey and bristling with concrete, and here you should enjoy a good story with a pinch of salt. From a distance the island genuinely looks like a warship at anchor, with what could pass for a bridge and gun turrets, and the popular tale is that its defences were deliberately built that way to fool the enemy into thinking a battleship guarded the firth. It is a wonderful idea, but historians who have looked find no evidence for it. The structures sit where they do to give the guns their best field of fire and to cram in the garrison. The resemblance is a happy accident, though a convincing one.

Watch too for a slender tower apparently standing in the open sea about halfway to Inchcolm. That is the Oxcars lighthouse, marking a reef of rocks that has holed many a hull, near others with the lovely names of the Cow and the Calf. Closer to the Edinburgh shore lies Cramond Island, joined to the mainland by a tidal causeway lined with a marching row of concrete anti-boat pylons, another piece of the wartime defences, and a place where careless walkers still get cut off and rescued by the rising tide with tedious regularity. And far out toward the open sea, beyond the day's horizon, lie the two crown jewels, the Isle of May with its enormous seabird colonies, and the Bass Rock, whitened by the largest gathering of gannets on the planet. A firth full of islands, each a small kingdom of stone.

The Wild Tenants of the Firth

For all the history stacked on these islands, do not spend the whole crossing looking at bridges and battlements, because the Firth is one of the great wildlife estuaries of Britain, and the show is often happening just off the rail. This is a rich larder, a broad tidal firth stiff with fish, ringed by rocky skerries that make perfect refuges, and the wildlife has been exploiting it far longer than the monks or the gunners ever did.

Watch the low rocks and buoys for seals hauled out to rest, and the water around the boat for the smooth dark heads that surface, stare, and slip under again, sometimes trailing the ferry out of pure curiosity. Two different seals share this water, and it is worth learning to tell them apart. Overhead and on the island itself, expect eider ducks, terns, and gulls, the last of them thoroughly emboldened in July, when there are chicks to defend.

One honest word about puffins, since everyone hopes for them. You may glimpse a few whirring past on their fast little wings, but Inchcolm is not really their island. The great puffin city lies further out at the Isle of May, and the planet's largest gannet colony further still on the Bass Rock. Here, the stars are the seals and the eiders. So keep half an eye on the sea the whole way over. Every splash, every bobbing head, is one of the firth's oldest residents going about its business.

Seals: Grey and Harbour

The seals you see lolling on the skerries around Inchcolm come in two species, and once you can tell them apart, the whole firth becomes more legible. The commoner and larger here is the grey seal, and it wears a wonderfully unglamorous scientific name, *Halichoerus grypus*, which translates more or less as hook-nosed sea pig. The clue is in the face. A grey seal has a long, straight, Roman profile, the forehead and the nose running down in one heavy sloping line, rather like a horse or a large dog seen from the side. The bulls are enormous, a big one can outweigh a family car, and they carry battle scars on their thick necks from fighting over breeding beaches. Britain is a genuine stronghold for them, hosting a very large share of the world's grey seals, so these are not a scrap of local colour but a population of real global importance.

The other is the harbour seal, also called the common seal, though it is actually the scarcer of the two in many Scottish waters. It is smaller and rounder-faced, with a short, almost cat-like or spaniel muzzle and nostrils set in a neat V, altogether a gentler-looking animal. The surest difference is hidden in the calendar. Grey seals pup in the autumn and early winter, and their pups are born in a coat of white fluff and cannot swim for weeks. Harbour seals pup in June and July, and their pups are miracles of readiness, able to swim and dive within hours of birth, which they must, because they are born on tidal sandbanks and rocks that the sea will shortly reclaim. So a small seal pup swimming beside its mother in high summer is almost certainly a harbour seal.

What you are mostly watching, though, is seals doing very little, and that idleness has a purpose. Hauling out on a rock at low tide lets them rest, digest a bellyful of fish, escape the cold water, and keep an eye out for danger, all at once. In the water they are transformed, fast, silent and endlessly nosy. If a smooth head surfaces astern and simply watches the boat, hanging upright in the water in a posture the biologists actually call bottling, you have been noticed. The seal is studying you quite as carefully as you are studying it.

The Seabird City

The birds of the Forth deserve a closer look than most visitors give them, and one in particular carries a lovely thread of history. Watch the water near the island for eider ducks, big, low-riding sea ducks that ride the swell in little flotillas. The drakes are unmistakable once you catch the light, boldly patterned in black and white with a wash of soft green on the neck and a breast tinged pink, while the females are a beautifully camouflaged warm brown. Listen, too, for the sound the males make in spring, a soft, rising, almost comical cooing, a sort of astonished ooh that carries over the water. The eider is Britain's heaviest duck and, in level flight, among its fastest, and its down, the insulating feathers the female plucks from her own breast to line the nest, is the eiderdown that once filled the warmest quilts in Europe.

Here is the history. On the Farne Islands down the coast, the eider is known as the cuddly duck, Saint Cuthbert's duck, because in the seventh century the hermit-bishop Cuthbert gave the nesting eiders his protection, and that is often called one of the earliest wildlife protection laws anywhere in the world. So these tubby, cooing ducks have been under a saint's care for thirteen hundred years, a fitting neighbour for an island of monks.

Around them wheel the terns, the sea swallows, all knife-edged wings and forked tails, some of which will fly to the Antarctic and back within the year, the longest migration of any animal on Earth. And then there are the gulls, which bring the day's one practical warning. In July the herring gulls and the big lesser black-backed gulls have chicks on the ground, grey fluffy things tucked among the ruins and the grass, and the parents defend them with real conviction. They will dive at anyone who strays too near, swooping low over your head with a great deal of noise. It is far more alarming than dangerous. Keep to the marked paths, and if a gull decides you are a threat, simply hold a hand or a hat up above your head, because they aim for the highest point and would much rather buzz that than your scalp. Consider it the island's coast guard, still on duty, long after the human garrison sailed home.
